Problem:- Given n and m. n = no. of strings in dictionary
m = no. of queries.
only 3 characters in string - a, b, c
find whether query[i] is present in dictionary & differ exactly one position.

Approach:- → Store all dictionary string in unordered set
→ for each query,
for each index,
* temporarily change character.
* check if new string exists
* Restore character.

Code:-
```
· input n, m;
· create unordered hash set
for (i = 1 ⟶ n){
        insert in set
}

for (each query of m queries){
        found = false;
        for (i = 0 to length (query) - 1){
                original Char = query[i];
                for each char in [a, b, c]:
                        if c == original Char
                                continue
                        query[s[i]] = c;
                if query string exists in set:-
                        found = true; break;
if found cout << "Yes";
else cout << "No";
```

Time Complexity:- O(S+T) Space Complexity:- O(S)
